**Abstract** - In digital era, cybercrime become a business. Nowadays, cyberattacks cause loss of sensitive data and severe financial loss to organizations. Therefore, cybersecurity expert's role is very important to protect the data from attacks. Researchers focus on intrusion detection to detect those unknown attacks. Machine learning algorithms plays a vital role in intrusion detection since it detects attacks accurately. The datasets used in most of the literature for intrusion detection are KDD Cup 99, NSL-KDD, UNSW-NB15, Kyoto and CSCIDS 2017. The detailed analysis of the datasets is discussed. The performance metrics used for evaluating the machine learning algorithms are also discussed. This study will be helpful for researchers to develop an efficient intrusion detection system.

#### Key Words: Intrusion Detection, Machine Learning, KDD Cup 99, NSL-KDD, Kyoto, UNSW-NB15, Accuracy

# **1. INTRODUCTION**

Nowadays businesses and governments deal with huge amount of data which is stored in computers and transmit across various networks to other systems. Due to the usage of huge amount of data, there is a possibility of data breach. Cyber security which plays a major role in defending various resources such as computers, mobile devices, networks, servers and data from variety of malicious attacks. Cyber security is also named as information technology security or electronic communication security. Cyber security is defined as the variety of technologies, processes and methods to protect the confidentiality, integrity, and availability of resources, against cyber-attacks or unauthorized access. The main aim of cyber security is to protect all organizational assets from both internal threats and external threats as well as disruption caused due to various natural disasters.

# 1.1 Various domains in cyber-security

(i) Application Security: It focuses to keep the software resources as free of threats. It implements the system as a secure one by designing the secure application architecture, writing the code as more secure one, implement the strong

data input validation process and various threat modeling in order to minimize the chances of any unauthorized access or modifying the application resources

(ii) Identity Management and Data Security: Within the organization, it includes the framework, processes and other activities which enable the process of authentication and the authorization of legitimate users to information systems.

(v)Mobile Security: Organizational information and personal information are stored in mobile devices like cell phones, laptops, tablets, etc. from various threats such as unauthorized access, device loss or theft, malware, etc. Mobile security which provides the technique to secure the data in various mobile devices.

(vi) Disaster recovery and business continuity: It deals with the process of how the organization is going to deal with the cyber-security incident or any other disaster which causes the loss of operations on data.

(vii)Cloud Security: It is used to secure the data which is stored in various cloud providers storage such as AWS, Google, Azure, etc.

# **1.2 Intrusion Detection**

Intrusion detection system are classified based on source of data and detection methodology. The classification of intrusion detection is depicted in Fig. 1. If the intrusion is monitored on hosts or devices on the network, then it is called Host intrusion detection systems (HIDS). In networkbased IDS, the intrusion is monitored on the whole network.

Based on detection methodology, IDS is classified into signature based and misuse-based approach. In a misuse detection approach, abnormal behavior of network is matched against known patterns of detected attacks. Anomaly based detection determines the unusual network traffic.

Fig- 1: Classification of Intrusion detection

# 2. METRICS USED TO EVALUATE INTRUSION DETECTION SYSTEM

The performance evaluation of any intrusion detection system can be done by the metrics such as: accuracy (ACC), Recall (REC), Precision (PRE), True Negative Rate (TNR), False Alarm Rate (FAR), False Negative Rate (FNR), F-Measure, Mathews Correlation Coefficient (MCC), ROC Graph and Kappa Statistics. The metrics required for evaluation are computed from confusion matrix (Table-1). A matrix that describes the performance of a given classification model (or "classifier") is called confusion matrix. It denotes true and false classification results. The ways in which confusion is made when a prediction is done by the classification model is depicted by confusion matrix.

|              |                       | Predic                | ted Class             |
|--------------|-----------------------|-----------------------|-----------------------|
|              |                       | Class 1<br>(Positive) | Class 2<br>(Negative) |
| Actual Class | Class 1<br>(Positive) | TP                    | FN                    |
|              | Class 2<br>(Negative) | FP                    | TN                    |

#### Table- 1: Confusion matrix

True positive (TP): It is the number of correctly identified anomaly records. False positive (FP): It represents the no. of incorrectly identified usual records that are detected as anomaly. True Negative (TN): It represents the number of correctly detected records. False Negative (FN): It shows the number of incorrectly detected anomaly records. **Accuracy (ACC):** It is the ratio of correct classification done by a classifier.

$$ACC = \frac{TP + TN}{TP + TN + FP + FN}$$

Sensitivity, REC (Recall), hit rate, detection rate or True Positive Rate (TPR): It measures the proportion of positives that are exactly identified as positives. It gives the ratio of correctly identified records to the total number of abnormal records.

$$TPR = \frac{TP}{TP + FN}$$

**Precision (PRE):** It is the ratio of correctly classified records over predicted positive cases.

$$Precision = \frac{TP}{TP + FP}$$

**Specificity, True** -ve **Rate (TNR):** It quantifies the fraction of negatives that are exactly identified as negatives.

$$TNR = \frac{TN}{TN + FN}$$

**False** +<sup>ve</sup> **Rate (FPR) or False Alarm Rate (FAR):** It gives the percentage of negative records that were incorrectly classified as positive.

$$FPR = \frac{FP}{FP + TN} = 1 - sensitivity$$

**False Negative Rate (FNR):** It is the percentage of positive records that were incorrectly classified as negative.

$$FNR = \frac{FN}{FN + TN} = 1 - TPR$$

**F-measure (F-Score):** It gives the sensitivity and precision of the harmonic mean.

$$F = \frac{2}{\left(\frac{1}{\text{recall}}\right) + \left(\frac{1}{\text{Precision}}\right)} = \frac{2 \times \text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} = \frac{2 \times \text{TP}}{2 \times \text{TP} + \text{FP} + \text{FN}}$$

General formula for positive real  $\beta$  is:

$$F = \frac{(1+\beta)^2 \times \text{Recall} \times \text{Precision}}{\beta^2 \text{Precision} + \text{Recall}}$$
$$= \frac{(1+\beta)^2 \times P \times TP}{\beta^2 \times P + TP}$$

**G-Mean1:** It is the geometric mean of precision and true positive rate.

G-Mean1=
$$\sqrt{TP * P}$$

**G-Mean2:** It is the geometric mean of true positive rate and true negative rate.

G-Mean2= $\sqrt{TP * TN}$ 

**Matthews correlation coefficient (MCC):** It measures the quality of binary classifications. It returns a value between -1 and +1.

 $MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP) \times (TP + FN) \times (TN + FP) \times (TN + FN)}}$ 

**Receiver operating characteristic (ROC) Graph:** A ROC graph examines the performance of classifiers. A ROC graph plots false alarm rate in the horizontal(X) axis and the sensitivity in the vertical(Y) axis.

**Kappa statistic:** It is the comparison between observed accuracy and expected accuracy (random chance). Observed accuracy is the count of exactly classified instances throughout the confusion matrix. Expected accuracy gives the accuracy that any classifier can achieve from the confusion matrix.

 $Kappa = \frac{observed \ accuracy - expected \ accuracy}{1 - expected \ accuracy}$ 

# 3. DATASETS USED FOR INTRUSION DETECTION RESEARCH

Most researchers used the datasets DARPA, KDD (Knowledge Discovery and Data Mining) Cup and NSL-KDD (Network Security Laboratory-KDD), UNSW-NB15, Kyoto and CSCIDS 2017 for intrusion detection. The datasets used for intrusion detection by researchers have both training data and testing data. The data set size comparison of training and test data for different datasets is shown in Table- 2.

Table- 2: Data Size comparison for different datasets

| Dataset       | Training size   | Testing size  |
|---------------|-----------------|---------------|
| DARPA 99      | 6.2GB           | 3.67GB        |
| KDD99         | 4898431bytes    | 311029 bytes  |
| NSL-KDD       | 125973 bytes    | 22444 bytes   |
| UNSW-<br>NB15 | 175,341 bytes   | 82,332 bytes  |
| AWID          | 1,795,575 bytes | 575,643 bytes |

#### 3.1 DARPA

The first standard corpus for the evaluation of intrusion detection system was created by MIT Lincoln Laboratory's in 1998 under the sponsorship of DARPA [1].

Lippmann et al. [2] developed a normal traffic scenario which is quite analogous to users of nearly 100's working on 1000's of workstation using intrusion detection evaluation test bed. The observations showed that detection rates were worse for new and novel R2L and DoS attacks.

The second DARPA off-line intrusion detection evaluation was done in 1999. Lippmann et al. [2] analyzed training data for three weeks and test data for two weeks and they found that over 200 instances of 58 attack types were launched in UNIX and Windows NT hosts. The major drawback is among 58 attack types; nearly ten attacks were not identified by any system because TCP services protocols and were not properly analyzed.

## 3.2 KDD Cup 99

The tcpdump portions (about 4 GB compressed tcpdump data for network traffic of 7 weeks of the 1998 DARPA Intrusion Detection System (IDS) Evaluation dataset were processed to create the dataset namely KDD Cup 99 [3] which was created by Lincoln Lab under contract to DARPA [4]. The data contains four main categories of attacks namely DoS (Denial of Service), U2R (User to Root), R2L (Remote to Local) and probing attack. DOS attack is an attack which denies resources. In U2R, user attacks gain root access through user account. R2L is a type of attack which sends packet through the network by gaining local access of the host as a user. Probing Attack attempts to gather information about a network of computers. Each connection records include traffic, intrinsic and content features.

Tavalee et al. [5] have analyzed KDD dataset in detail. KDD'99 features can be classified into three groups' namely basic, traffic and content features. The major problem in this dataset is the enormousness of duplicate records. They analyzed both test and training sets and reported that nearly 75% and 78% of the records are redundant. Due to these huge redundant records, during training the learning algorithms are biased towards more repeated records. It stops learning from records that are used infrequently which can cause harm to networks. The detection rates for these frequent records are better.

L

e-ISSN: 2395-0056 p-ISSN: 2395-0072

Atilla O et al. [6] analyzed KDD dataset and found that it consists two weeks of attacks-free instances and five weeks of attack instances. The dataset has a total of 38 attacks which includes 24 attack types in training and 14 more attack types in testing. Therefore, machine learning based IDS find it's difficult to detect these 14 new attacks. Only limited attacks are found under U2R and R2L.Since KDD99 is a large dataset for most machine learning algorithms, most researchers used a small percentage of it. This dataset is mainly used for anomaly type of intrusion. They tabulated the comparisons of training and testing size of different attacks.

Volume: 08 Issue: 04 | Apr 2021

IRJET

Out of the 42 features/attributes in this data set (Table- 3), 41 attributes can be categorized into 4 different classes namely basic, content, traffic and host features. The value type is either continuous(C)/ discrete(D).The different types of attacks in KDD dataset are shown in Fig-3.

| Table- 🛛 | 3: | Features | of KDD | dataset |
|----------|----|----------|--------|---------|

**Fig- 3:** Types of attacks in KDD dataset

L

# 3.3 NSL-KDD

Tavallaee et al [5] published the NSL-KDD dataset in their website [7] which is more beneficial than the original KDD data set. It eliminates duplicate records in training set thereby overcoming the drawback of classifiers gets biased towards more frequent records. Reasonably the number of records in train and test sets are selected which executes the complete set affordably. Only 20% of training data with total instances 25192 was identified as KDDTrain+\_20Percent.The test data set named KDDTest+ has a total of 22544 instances.

#### 3.4 UNSW-NB15 dataset

Due to absence of modern attack styles and traffic situations in KDD dataset, a new dataset (UNSW-NB15)[8] was developed by ACCS-an American Cyber security Center. This dataset has a 49-feature set and a total of 2,540,044 records [9]. The features in this dataset are tabulated in Table- 4. The types of attacks are shown in Table-5.

| Feat           | Featur | Description                  |  |  |
|----------------|--------|------------------------------|--|--|
| ure            | e Name |                              |  |  |
| No.            |        |                              |  |  |
| Flow features  |        |                              |  |  |
| 1              | Srcip  | Source" IP address"          |  |  |
| 2              | Sport  | Source "Port address"        |  |  |
| 3              | Dstip  | Destination " IP address"    |  |  |
| 4              | Dsport | Destination "Port number"    |  |  |
| 5              | Proto  | Type of protocol (UDP, TCP)  |  |  |
| Basic features |        |                              |  |  |
| 6              | State  | Indicates "state " and " its |  |  |
|                |        | dependent protocol"          |  |  |
|                |        | (CLO,ACC, and CON).          |  |  |
| 7              | Dur    | Total duration of            |  |  |
|                |        | connection                   |  |  |

|                               | d N       | Post in http service          |
| 39                            |           | If ftp session is login using |
|                               | is_ttp_lo | user and password then 1 is   |
|                               | gin       | set. otherwise, 0 is set      |
| 40                            |           | No of flows that has a        |
|                               | ct_ttp_c  | command in ftp session        |
| 41                            | ma        | No of records that have       |
| TI                            | ct srv s  | same" service" and "srcin"    |
|                               | rc        | in "100 records" based on "   |
|                               |           | ltime "                       |
| 42                            |           | No. of records that have      |
|                               | ct_srv_d  | same "service" and "dstip"    |
|                               | st        | in "100 records" based on     |
|                               |           | "ltime"                       |
| 43                            |           | No. of records of the same    |
|                               | ct_dst_lt | "dstip" in "100 records"      |
|                               | m         | based on "ltime"              |
| 44                            | ct_src_   | No. of records of "srcip" in  |
|                               | ltm       | "100 records" based on        |
|                               |           | "ltime"                       |
| 45                            |           | No of records of the same     |
|                               | ct_src_d  | "srcip" and " dsport" in      |
|                               | port_It   | "100 records" based on        |
|                               | 111       | "ltime"                       |
| 46                            |           | No. of records of the same    |
|                               | ct_dst_s  | "dstip" and "sport" in "100   |
|                               | m         | records" based on "ltime"     |
| 47                            |           | No. of records of the same    |
|                               | ct_dst_s  | "srcip" and "dstip" in "100   |
|                               | rc_ltm    | records" based on the         |
|                               |           | "ltime"                       |

Table-5: Attack Types in UNSW-NB15 dataset

| Attack Types   |
|----------------|
| Fuzzers        |
| Analysis       |
| Backdoor       |
| Dos            |
| Exploit        |
| Generic        |
| Reconnaissance |
| Shellcode      |
| Worm           |

## 3.5 Kyoto 2006+ dataset

Kyoto dataset [10] is created from real environment traffic data collected from honey pot over 3 years. It has 24 statistical features, 14 features derived from KDD dataset and 10 from other analysis done on NIDS [11]. Researchers are capable to obtain more accurate results during their evaluation. The description of features in Kyoto dataset are shown in Table -6.

#### **Table-6:** Features of Kyoto dataset

| Feature | Description                   |
|---------|-------------------------------|
| 1       | Duration                      |
| 2       | Service                       |
| 3       | Source bytes                  |
| 4       | Destination bytes             |
| 5       | Count                         |
| 6       | Same srv rate                 |
| 7       | Serror rate                   |
| 8       | Srvserror rate                |
| 9       | Dst host count                |
| 10      | Dst host srv count            |
| 11      | Dst host same src port        |
| 12      | Dst host serror rate          |
| 13      | Dst host srvserror rate       |
| 14      | Flag                          |
| 15      | IDS detection                 |
| 16      | Malware detection             |
| 17      | Ashula detection              |
| 18      | Label                         |
| 19      | Source IP Address             |
| 20      | Source Port Number            |
| 21      | <b>Destination IP Address</b> |
| 22      | Destination Port              |
| 23      | Start Time                    |
| 24      | Duration                      |

#### 3.6 CSCIDS 2017

A reliable and real-world dataset namely CICIDS2017[12] has benign and seven common attack network flows namely Brute Force Attack, Heartbleed Attack, Botnet, DoS Attack, DDoS Attack, Web Attack and Infiltration Attack with 80 features. They used CICFlowMeter to extract the data from pcap file. The label for each flow is FlowID, SourceIP, DestinationIP, SourcePort, DestinationPort, and Protocol.

## 4. CONCLUSION

Mostly Intrusion detection based on Machine learning and deep learning literatures used the benchmark datasets such as KDD Cup 99, NSL-KDD, UNSW-NB15, Kyoto and CSCIDS 2017. Most of the datasets used for research lack in real traffic data. Most of the organisations do not release the network traffic due to confidentiality issue. Therefore, there is a huge demand for real time network traffic data. The performance metrics is important in checking the effectiveness of an algorithm. Researchers can develop an efficient IDS only when a real time attack scenario are provided which incorporates innovative attacks.
